

How does a biological carbon pump contribute to ocean carbon storage?

The biological carbon pump contributes to ocean carbon storage by moving organic carbon out of the surface ocean into deeper waters in sinking particles, vertically migrating organisms and physical circulation.

Why do we need a carbon storage system?

They are central to investments that can increase carbon storage in the terrestrial biosphere and make meaningful progress towards meeting international climate goals. Quantifying the effects of the full range of constraints is difficult at a global scale.

What is a carbon storage program?

(Elsevier Ltd.) The Carbon Storage Program contains three principal components: Core Research and Development (R&D), Infrastructure, and Program Support (Strategic). Core R&D involves both applied lab.- and pilot-scale research focused on adapting existing and developing new technologies and systems for geol. storage.

How do ecosystems sequester and store carbon?

Through photosynthesis, ecosystems naturally sequester and store carbon. Enhancing these processes forms the basis of biological sequestration strategies. Ecosystems are a sink of atmospheric CO<sub>2</sub> and significantly impact the global carbon cycle.

How do Natural Ecosystems store carbon?

Provided by the Springer Nature SharedIt content-sharing initiative Natural ecosystems store large amounts of carbon globally, as organisms absorb carbon from the atmosphere to build large, long-lasting, or slow-decaying structures such as tree bark or root systems.

What is underground storage of CO<sub>2</sub>?

Underground storage of CO<sub>2</sub> involves the injection of CO<sub>2</sub> into suitable geol. formations and the monitoring of the injected plume over time, to ensure containment. Over the last two or three decades, attention has been paid to technol. developments of carbon capture and sequestration. Therefore, it is high time to look at the research done so far.

1. Introduction [2] Volk and Hoffert define an ocean carbon pump as "a process that depletes the ocean surface of dissolved inorganic carbon (DIC) relative to the deep-water DIC." They recognized three such pumps: the soft-tissue pump, the carbonate pump and the solubility pump. While the first two are biological, the third is a response to solubility ...

3.1 Ocean Carbon Sequestration. Carbon dioxide is stored in plants such as grasslands and forests, as well as soils and oceans, as part of the biological NET. The oceans contain an estimated 38,000 gigatons of carbon,

making them the largest C pool (McLeod et al. 2011). Ocean carbon sequestration is a technique where throughout the ocean depth, there is ...

In forests, stand age is a major driver of differences in carbon storage in temperate and tropical forests, with older forests storing more carbon 27, hence the separation of older ( $\geq 100$  years ...

Throughout Earth's history, microbial processes have been the key drivers in controlling atmospheric concentrations of greenhouse gases (GHGs), including carbon dioxide, methane and nitrous oxide. Most importantly, these microorganisms will continue to influence greenhouse biogenic gas flux either by amplifying or reducing the rate of climate change. It is up to us to ...

Another potential production system for bioenergy with biological carbon capture and storage (BECCS) is the large-scale cultivation of seaweed (macroalgae) for biofuels. Marine biofuels offer considerable advantages over terrestrial first-generation biofuels in terms of their low land use, fresh water and fertilizer requirements.

The transfer of organic carbon from the upper to the deep ocean by particulate export flux is the starting point for the long-term storage of photosynthetically fixed carbon. This "biological ...

Carbon capture and storage (CCS), Carbon capture and utilization (CCU) are the two technologies adapted to capture the atmospheric CO<sub>2</sub>, utilize it, and focus on permanent ...

Carbon sequestration, the long-term storage of carbon in plants, soils, geologic formations, and the ocean. In response to concerns about climate change resulting from increased carbon dioxide concentrations in the atmosphere, interest has been drawn to geoengineering techniques such as carbon capture and storage. ... The biological and ...

1 Introduction. The biological carbon pump is a collection of processes that transport organic carbon from the surface ocean to depth. It is responsible for roughly 2/3 of the surface-to-deep gradient in dissolved inorganic carbon (DIC) in the ocean (Sarmiento & Gruber, 2006) and thus plays an important role in regulating Earth's carbon cycle and climate (Kwon et ...

Assessing the carbon storage capacity of terrestrial ecosystems is crucial for land management and carbon reduction policymaking. There is still a knowledge gap regarding how ecosystem carbon storage will be impacted by combined environmental and land-use factors and their spatial-temporal changes, especially in developed regions where urbanization has ...

Natural ecosystems store large amounts of carbon globally, as organisms absorb carbon from the atmosphere to build large, long-lasting, or slow-decaying structures such as tree bark or root systems.

Soil carbon storage is a vital ecosystem service, resulting from interactions of ecological processes. Human

activities affecting these processes can lead to carbon loss or improved storage. Aa Aa ...

1 Introduction. Natural ocean carbon storage is driven by the biological carbon pump (BCP) via carbon export and the solubility pump via the subduction of dissolved inorganic carbon enriched waters (Volk & Hoffert, 1985). The BCP mediates the transfer of photosynthetically produced particulate organic matter from the surface ocean to the ocean ...

The biological carbon pump is an important process of natural carbon sequestration in the ocean 1,2,3,4,5,6. Photosynthesis in sunlit surface waters converts dissolved inorganic carbon (DIC) into ...

This report provides results of a rapid assessment of biological carbon stocks and forest biomass carbon sequestration capacity in the conterminous United States. Maps available from the U.S. Department of Agriculture are used to calculate estimates of current organic carbon storage in soils (73 petagrams of carbon, or PgC) and forest biomass (17 PgC).

The increasing interest in bio-based construction materials has resulted in the emergence of the concept of "buildings as a carbon sink". Quantifying and comparing the effects of carbon sequestration and storage in buildings from a life cycle perspective involves the evaluation of flows and processes taking place at different timescales and across ecological, ...

Abstract. The present study aimed to evaluate the biological carbon storage potential of *Guiera senegalensis* stands in Cameroon. Sampling was done in 180 plots of 2500 m<sup>2</sup> (50 m × 50 m) (40 ha) in the *G. senegalensis* stands. The destructive and non-destructive method was used to estimate the amount of carbon in different biomasses.

A range of biological (e.g. deep-rooting), chemical (e.g. biochar burial) and physical (e.g. deep ploughing) C sequestration strategies have been proposed, but are yet to ...

These carbon pools are mediated by physical, chemical, biological and biogeochemical mechanisms known as the solubility carbon pump (SCP), microbial carbon pump (MCP) 3, biological carbon pump ...

The carbon storage of biological soil crusts in desert ecosystems is approximately 0.002 Pg, accounting for less than 1/1000 of the entire desert ecosystem's carbon pool (Tang et al. Citation 2018). Their relatively low contribution is due to the low carbon density resulting from their thin layer ...

Ocean carbon uptake could be affected by changes in circulation. This modelling study shows that meridional overturning circulation slowdown increases deep-ocean storage via the biological pump ...

Global fossil fuel use emits roughly 8 Pg carbon (C) y<sup>-1</sup> to the atmosphere (EIA 2011) cause the oceans and terrestrial biosphere take up only roughly 55 % of these emissions (Ballantyne et al. 2012), atmospheric carbon dioxide (CO<sub>2</sub>) concentrations are growing at roughly 2 ppm y<sup>-1</sup> (NOAA 2012). Given this trend,

strategies for atmospheric carbon dioxide removal ...

It should be noted that although calcification induces biological carbon storage, via sinking of particulate inorganic carbon (PIC) to the interior ocean, it also induces outgassing of CO<sub>2</sub> from the ocean surface, due to the imbalance in carbonate chemistry that it causes. Rain ratio is the ratio between the export of PIC and POC. Assessing ...

Geologic carbon sequestration is the process of storing carbon dioxide (CO<sub>2</sub>) in underground geologic formations. The CO<sub>2</sub> is usually pressurized until it becomes a liquid, and then it is injected into porous rock formations in geologic basins. This method of carbon storage is also sometimes a part of enhanced oil recovery, otherwise known as tertiary recovery, because it is ...

The biological pump drives carbon storage in the deep ocean and is thought to function via gravitational settling of organic particles from surface waters. However, the settling flux alone is ...

This is the case because a global decrease in the storage of carbon that is attributable to the biological carbon pump (termed "biological pump carbon" throughout), which is driven by a ...

This Review discusses the constraints and potential contributions of increasing carbon storage in the terrestrial biosphere, suggesting a conservative estimate of 100-200 ...

1. Introduction. Plant diversity has been shown to have a strong positive impact on ecosystem functioning and service provisioning [1-3]. Plant diversity loss due to global change and land-use change [4,5] can threaten ecosystem functioning [6,7], whereas restoration of plant diversity, such as afforestation of mixed forests, can increase ecosystem functioning [8,9].

Given these societal challenges and because CO<sub>2</sub> is nontoxic, nonflammable, plentiful, and a renewable carbon source, it has been utilized as a sustainable feedstock as part of multipronged approaches to decarbonize the atmosphere via capture and biological, chemical, and geological sequestration or storage. Carbon or CO<sub>2</sub> Capture and Storage ...

The ability to increase carbon storage in the terrestrial biosphere can be conceptualized as a spectrum from a "silo" -- wherein the capacity for increasing carbon storage is limited to ...

We use both theory and ocean biogeochemistry models to examine the role of the soft-tissue biological pump in controlling atmospheric CO<sub>2</sub>. We demonstrate that atmospheric CO<sub>2</sub> can be simply related ...
