The energy stored on a capacitor can be expressed in terms of the work done by the battery. Voltage represents energy per unit charge, so the work to move a charge element dq from the negative plate to the positive plate is equal to V dq, where V is the voltage on the capacitor. The voltage V is proportional to the amount of charge which is already on the capacitor.

The rechargeable C cell I mentioned above (1.2v, 2.2Ah) holds 9,500 joules. A capacitor holding this much energy at 1.2v would have to be $(2 \times 9,500 / 1.2 \times 1.2) = 13,000$ Farads, so if it helps, you can think of a battery as an enormous capacitor. Energy stored in a real capacitor - the earth!

The energy stored in a capacitor is the work done to move charge against the electric field between the plates.

It's an example of potential energy, which in this case, is stored in the electric field itself. Energy Density of a Charged Capacitor. Energy density is a measure of how much energy is stored in a given space.
