From the definition of voltage as the energy per unit charge, one might expect that the energy stored on this ideal capacitor would be just QV . That is, all the work done on the charge in moving it from one plate to the other would appear as energy stored. But in fact, the expression above shows that just half of that work appears as energy stored in the capacitor.

Capacitor energy storage systems can be classified into two primary types: Supercapacitors and Ultracapacitors. The energy stored on a capacitor can be expressed in terms of the work done by the battery. Voltage represents energy per unit charge, so the work to move a charge element dq from the negative plate to the positive plate is equal to $V dq$, where V is the voltage on the capacitor. The voltage V is proportional to the amount of charge which is already on the capacitor.
