DMA is used for measurement of various types of polymer materials using different deformation modes. There are tension, compression, dual cantilever bending, 3-point bending and shear modes, and the most suitable type should be selected depending on the sample shape, modulus and measurement purpose.

the storage modulus, E", a measure of how elastic the material acts under these conditions of tempera-ture, load, and frequency. The lost height can be related to the loss modulus, E". This is illustrated in Figure 2. The ratio of the loss modulus to the storage modulus is also the tan of the phase angle and is called damping: Damping =  $\tan \dots$

Peak on Tan Delta curve ; Peak on Loss Modulus curve ; Half height of Storage Modulus curve ; Onset of Storage Modulus curve ; It is important when reporting Tg by DMA to specify how the Tg was determined because the difference between the different techniques can vary as much as 25°C. Tg by DMA is often about 10°C higher than DSC Tg.

The elastic modulus is measured as the shear storage modulus, G?, and loss modulus, G?. Tan delta, the loss factor, or the damping coefficient, G?/G?, is calculated by using this data. When compared to other methods, DMA is considerably more sensitive.

The dynamic mechanical analysis method determines [12] elastic modulus (or storage modulus, G"), viscous modulus (or loss modulus, G?), and damping coefficient (tan D) as a function of temperature, frequency or time. Results are usually in the form of a graphical plot of G", G", and tan D as a function of temperature or strain.
