How is energy stored in an inductor?

The energy stored in an inductor is directly related to both its inductance and the amount of current flowing through it. The formula for energy storage, $U = \frac{1}{2} L I^2$, shows that energy increases with the square of the current.

What is an inductor & how does it work?

What are Inductors? An inductor, physically, is simply a coil of wire and is an energy storage device that stores that energy in the electric fields created by current that flows through those coiled wires. But this coil of wire can be packaged in a myriad of ways so that an inductor can look like practically anything.

What factors affect the energy storage capacity of an inductor?

The energy storage capacity of an inductor is influenced by several factors. Primarily, the inductance is directly proportional to the energy stored; a higher inductance means a greater capacity for energy storage. The current is equally significant, with the energy stored increasing with the square of the current.

Why is an inductor discharging?

In this condition, the inductor is said to be discharging, because its store of energy is decreasing as it releases energy from its magnetic field to the rest of the circuit. Note the polarity of the voltage with regard to the direction of current.

What happens if an inductor stores more energy?

As an inductor stores more energy, its current level increases, while its voltage drop decreases. Note that this is precisely the opposite of capacitor behavior, where the storage of energy results in an increased voltage across the component!

Why is an inductor charging?

When the current through an inductor is increased, it drops a voltage opposing the direction of current flow, acting as a power load. In this condition, the inductor is said to be charging, because there is an increasing amount of energy being stored in its magnetic field. Note the polarity of the voltage with regard to the direction of current:
