The transition towards a low-carbon energy system is driving increased research and development in renewable energy technologies, including heat pumps and thermal energy storage (TES) systems [1]. These technologies are essential for reducing greenhouse gas emissions and increasing energy efficiency, particularly in the heating and cooling sectors [2, 3].

The purpose of Energy Storage Technologies (EST) is to manage energy by minimizing energy waste and improving energy efficiency in various processes [141]. During this process, secondary energy forms such as heat and electricity are stored, leading to a reduction in the consumption of primary energy forms like fossil fuels [142].

The progress in the emerging technology of power semiconductor devices and its control methods has enhanced the flexibility of integrating DGs with the traditional grid [2].

In the past few decades, electricity production depended on fossil fuels due to their reliability and efficiency [1]. Fossil fuels have many effects on the environment and directly affect the economy as their prices increase continuously due to their consumption which is assumed to double in 2050 and three times by 2100 [6] g. 1 shows the current global ...
