In active balancing circuits, the energy is transferred among the cells (through small shunt currents) by using extra storage components such as capacitors and inductors, whereas in passive balancing circuits, resistors are utilised to dissipate excess energy of a cell (Liu et al., 2022a).

Capacitors store energy in electric fields between charged plates, while inductors store energy in magnetic fields around coils. The amount of energy stored depends on capacitance or inductance and applied voltage or current, respectively.
