

Is power dissipation related to energy storage?

Both power dissipation and energy storage are related, since electric and magnetic fields can store energy. However, for nonmagnetic materials, only electric current can result in power dissipation. Understanding this relationship may offer deep insight into the radiative properties of nanostructures.

What temperature do inductors need to be insulated?

Most inductors presently use at least 130°C or 150°C insulation types. As with other parameters it is important to know the inductor temperature rise so this can be traded off with other parameters when making design choices. If lower temperature rise is desired, a larger size component is most likely the answer.

How do you know if an inductor is heating up?

Given rated current is a good way to estimate an inductor's temperature rise. Temperature increase is also influenced by the circuit design PCB layout, proximity to other components, and trace dimensions and thickness. Additional heat may also be caused by an excess of AC loss generated in the inductor core body and winding.

What is inductor loss?

Inductor loss is closely related to core size and wire size. In many cases, lowest loss corresponds to larger part size, or it corresponds to using a hard-saturation core material. As with any design, there may be compromises that require analyzing trade-offs in size or inductance at peak current vs efficiency.

Why do inductor windings have a high resistance?

This is a parameter that is not commonly shown on inductor data sheets and is not typically a concern unless either the operating frequency or the AC component of the current is large with respect to the DC component. The resistance of most inductor windings increases with operating frequency due to skin effect.

What is the dissipation density associated with Ohmic conduction?

The dissipation density associated with Ohmic conduction is $I^2 R$. An Ohmic current can be imposed by making electrical contact with the material, as for the heating element in a stove. If the material is a good conductor, such currents can also be induced by magnetic induction (without electrical contact).

Manufacturers may also implement specialized insulation techniques to manage heat dissipation and protect the winding wire from potential damage.
