An inductor, also called a coil, choke, or reactor, is a passive two-terminal electrical component that stores energy in a magnetic field when electric current flows through it. [1] An inductor typically consists of an insulated wire wound into a coil. When the current flowing through the coil changes, the time-varying magnetic field induces an electromotive force (emf) in the conductor ...

An inductor is a device whose purpose is to store and release energy. A filter inductor uses this capability to smooth the current through it and a two-turn flyback inductor employs this energy storage in the flyback converter in-between the pulsed current inputs.
