LC Circuit - Key takeaways. An LC circuit is made up of an inductor (a solenoid) and a charged capacitor. The charged capacitor discharges its electrical energy over time, allowing for a current to pass through the solenoid. The solenoid then produces a magnetic field.

Show that the total energy in the LC circuit remains unchanged at all times, not just when all the energy is in the capacitor or inductor. Solution. The energy stored in the system at a time (t) is the sum of the energies stored in each device:

The LC circuit uses the energy storage characteristics of capacitors and inductors to alternately convert electromagnetic energy. That is to say, electric energy and magnetic energy will have a maximum and minimum values, and there will be oscillation. However, this is only an ideal situation. Virtually all electronic components will lose energy.

The reason why the LC oscillator circuit oscillates is that the circuit uses the energy storage devices of capacitors and inductors to alternately convert electromagnetic energy.

We develop an intuition for the natural response of the inductor-capacitor $(text{LC})$ circuit. Circuits with two energy storage elements (capacitors or inductors) are called second-order systems. The voltage and current rock back-and-forth, or oscillate. Second-order systems are where sine waves come from in analog circuits.
