

What are energy storage capacitors?

Capacitors exhibit exceptional power density, a vast operational temperature range, remarkable reliability, lightweight construction, and high efficiency, making them extensively utilized in the realm of energy storage. There exist two primary categories of energy storage capacitors: dielectric capacitors and supercapacitors.

Do nanostructured storage devices increase capacitance density?

Nanostructured storage devices with 3D metal-insulator-metal (MIM) architectures--which require conformal metal and insulator deposition inside porous nanostructures--have successfully increased capacitance density, and therefore energy storage, per unit planar area (Fig. 3b, Supplementary Table 3).

Are NC HZO superlattice films suitable for 3D Si capacitors?

Ultimately, the ferroic-engineered NC HZO superlattice films integrated into 3D Si capacitors demonstrate record energy storage ( $80 \text{ mJ cm}^{-2}$ ) and power density ( $300 \text{ kW cm}^{-2}$ ), to our knowledge, across all dielectric electrostatic capacitors.

Can electrostatic capacitors provide ultrafast energy storage and release?

Electrostatic capacitors can enable ultrafast energy storage and release, but advances in energy density and efficiency need to be made. Here, by doping equimolar Zr, Hf and Sn into  $\text{Bi}_4\text{Ti}_3\text{O}_{12}$  thin films, a high-entropy stabilized  $\text{Bi}_2\text{Ti}_2\text{O}_7$  pyrochlore phase forms with an energy density of  $182 \text{ J cm}^{-3}$  and 78% efficiency.

Can electrostatic capacitors amplify energy storage per unit planar area?

However, electrostatic capacitors lag behind in energy storage density (ESD) compared with electrochemical models 1,20. To close this gap, dielectrics could amplify their energy storage per unit planar area if packed into scaled three-dimensional (3D) structures 2,5.

It all has to do with the equation for the capacitive energy storage, namely the energy stored in a capacitor with capacitance  $C$  charged from a power supply at some constant potential  $V$  is given by:  $E=0.5*CV^2$ . This represents half of the energy drawn from the power supply during charging, with the other half being “used up” as the charging
