To assess the effect of the molten-salt TES on the flexibility of the CFPP, the power change factor θ , which represents the ratio of the power change of the unit caused by the molten-salt energy storage during cyclic operation to the rated power of the unit, is defined as follows:
$$\theta = \frac{D W_{ch} + D W_{dch}}{W} \times 100 \%, \quad C F P P \times 100 \% \quad (2)$$

The increase of electric power demand and the wish to protect the environment are leading to a change in the energy sources. Conventional energy plants are losing strength against the renewable energy plants and, in particular, solar energy plants have a huge potential to provide clean energy supply for the increasing world's energy demand.

Energy Storage Systems (ESSs) can absorb the intermittent wind power that would otherwise be fed into the grid and dispatch it as a schedulable, steadier and possibly uninterrupted power supply. Such an operation will allow operators to maximise profits by selling electricity during periods of high demand and avoiding curtailment.

The analysis further reveals a marked enhancement in the operational performance of the power system. Notably, as v increases, there is a consistent reduction in the operation risk cost, wind power curtailment, and load shedding. However, this is accompanied by a corresponding increase in the operational costs of the power system.
