 (P_{out}) is the output power, (P_{in}) is the input power. Generally speaking, the higher the efficiency, the better. This implies less waste. In other words, if a system is 30% efficient, then 70% of the input power is wasted, whereas if a system is 99% efficient, then only 1% of the input power is wasted.

Therefore, there exists an urgent demand to introduce systematic output regulation measures to engineer a TENG-based power supply equipped with energy storage and output regulation functionalities.

The generated wind power output is directly proportional to the cube of wind speed, P w = 1 / 2 r A v 3, where r is density, A is the area, and v is the velocity (wind speed). Since wind speed presents random fluctuations the wind output power will fluctuate and result in the issues of system stability and reliability.

Power output refers to the rate at which energy is produced or delivered by a system, often measured in watts (W). It is a crucial factor in determining how effectively a storage technology can provide energy when needed, influencing the performance and efficiency of various energy systems, including batteries, compressed air systems, and flywheels.
