

What is superconducting magnetic energy storage (SMES)?

Superconducting magnetic energy storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil that has been cryogenically cooled to a temperature below its superconducting critical temperature. This use of superconducting coils to store magnetic energy was invented by M. Ferrier in 1970.

What are superconductor materials?

Thus, the number of publications focusing on this topic keeps increasing with the rise of projects and funding. Superconductor materials are being envisaged for Superconducting Magnetic Energy Storage (SMES). It is among the most important energy storage systems particularly used in applications allowing to give stability to the electrical grids.

What components are used in superconducting magnetic energy storage?

Major components of the generation, transmission (power cables and devices for superconducting magnetic energy storage), distribution (transformers and fault current limiters) and end-use (motor) devices have been built, primarily using the  $(\text{Bi,Pb})_2\text{Sr}_2\text{Ca}_2\text{Cu}_3\text{O}_x$  (Bi-2223) conductor.

What is a superconductor configuration?

A configuration for which the magnetic field inside the system is at all points as close as possible to its maximum value is then required. This value will be determined by the currents circulating in the superconducting materials. Afterwards, the amount of superconductor to be used should be minimized as much as possible.

How to design a superconducting system?

The first step is to design a system so that the volume density of stored energy is maximum. A configuration for which the magnetic field inside the system is at all points as close as possible to its maximum value is then required. This value will be determined by the currents circulating in the superconducting materials.

The maximum capacity of the energy storage is  $E_{max} = \frac{1}{2} L I_c^2$ , where  $L$  and  $I_c$  are the inductance and critical current of the superconductor coil respectively. It is obvious that the  $E_{max}$  of the device depends merely upon the properties of the superconductor coil, i.e., the inductance and critical current of the coil. Besides  $E_{max}$ , the capacity realized in a practical ...
