

# The huge energy storage of internal circulation

How is energy stored in the body?

Energy is stored in the form of fat, and meets the demand of body via two coupled mechanisms: catabolism and oxidative phosphorylation. Under normal physiological conditions, fat consumption involves ketone body metabolism through the circulatory system and glucose consumption requires blood lactic acid cycle.

What is the relationship between blood flow and total energy?

There are two important concepts that follow from this relationship. Blood flow is driven by the difference in total energy between two points.

How does distorted blood flow affect energy loss?

Visualization and quantification of the adverse effects of distorted blood flow are important emerging fields in cardiology. Abnormal blood flow patterns can be seen in various cardiovascular diseases and are associated with increased energy loss.

What happens if energy substances exceed storage capacity?

When energy substances exceed storage capacity, the body initiates an "alarm signal", eliminates accumulated energy directly by improving catabolism or in the form of blood or urine glucose, promotes cell proliferation, produces excessive immunity, and even causes cancer. These processes are controlled by mTOR nutrient-sensing system.

Why does blood have kinetic energy?

Because flowing blood has mass and velocity, it has kinetic energy (KE). This KE is proportionate to the mean velocity squared ( $V^2$ ; from  $KE = \frac{1}{2} mV^2$ ). As the blood flows inside a vessel, pressure is exerted laterally against the walls of the vessel; this pressure represents the potential or pressure energy (PE).

What is long-term energy storage?

Long-term energy storage only involves conversion of glucose into fat, and this fat is majorly stored subcutaneously, especially under the belly. This storage method is of vital significance for biological adaptation, which not only provides energy to the body in the cold season when food shortage occurs but also effectively prevents heat loss.

2.1 Physical Principles. Thermal energy supplied by solar thermal processes can be in principle stored directly as thermal energy and as chemical energy (Steinmann, 2020) The direct storage of heat is possible as sensible and latent heat, while the thermo-chemical storage involves reversible physical or chemical processes based on molecular forces. ...

The radiocarbon content of seawater ( $^{14}C/C$ , commonly expressed as a  $^{14}C$  age or as  $D^{14}C$ ; see the Supplementary Materials for more information) has long been recognized as a "most useful tracer" of ocean circulation and ventilation. This is because  $^{14}C$  is introduced to the global ocean via the air-sea exchange of  $CO_2$ , and as surface waters ...

Total energy connotes the sum of the internal and mechanical (i.e., internal plus potential plus kinetic) energy, where the kinetic energy is ordinarily neglected, as justified in Exercise 5.4. Observational studies of the long-term mean global energy balance dating back to the 1950s demonstrate the central role of the poleward eddy heat transports.
