How do you calculate the energy density of a flywheel?

The maximum specific (per unit mass) energy density  $E_{sp}$  that can be stored in a flywheel may be written as  $E_{sp} = K_s \frac{\sigma_m}{\rho}$  where  $\sigma_m$  is the maximum tensile strength of the flywheel material,  $\rho$  the density of the flywheel, and  $K_s$  is the shape factor.

How do different flywheel structures affect energy storage density?

Different flywheel structures have important effects on mass distribution, moment of inertia, structural stress and energy storage density. Under a certain mass, arranging the materials as far away as possible from the center of the shaft can effectively improve the energy storage density of the flywheel rotor per unit mass.
