On a high level, flywheel energy storage systems have two major components: a rotor (i.e., flywheel) and an electric motor. These systems work by having the electric motor accelerate the rotor to high speeds, effectively converting the original electrical energy into a stored form of rotational energy (i.e., angular momentum).

The minimum speed of the flywheel is typically half its full speed, the storage energy is given by  $\frac{1}{2} I \omega^2$  where  $I$  is the rotor moment of inertia in  $\text{kgm}^2$  and the  $\omega$  maximum rotational speed in  $\text{rad/s}$ . The power level is controlled by the size of the M/G, so this is independent of the rotor.
